# Introduction

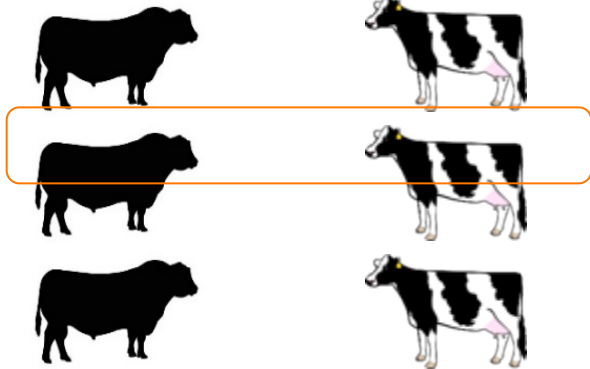

- Holstein-Friesian (HF) breed
  - Dominates production worldwide
  - Intense selection and AI
  - $N_e$  of 50-150
  
- Since 2009, genomic selection (GS):
  - GEBVs; exploit MS
  - Accelerated progress
  - **Effect on inbreeding?**

# Study objective

Assess how GS has affected inbreeding trends  
in Dutch-Flemish HF cattle

In AI-bulls & In cow pop.

Genome-wide & Region-specific

# Material & methods: data

- Pedigree & phased genotypes (~75 k):
  - 3,373 AI-bulls
  - 5,770 cows

# Material & methods: generation interval

- Sharp decrease for AI-bull sires with GS

# Material & methods: inbreeding measures

- Genome-wide:

1. Pedigree-based  $F_{PED}$  = expected IBD

2. Marker-based  $HOM_{SNP}$  = IBS

3. Segment-based  $F_{ROH}$  = realised IBD

➤  $\geq 3.75$  Mb

*Rate per generation ( $\Delta F$ )*

- Region-specific:

➤ Positional  $F_{ROH}$  for cohorts of 3y

# Results: genome-wide trends

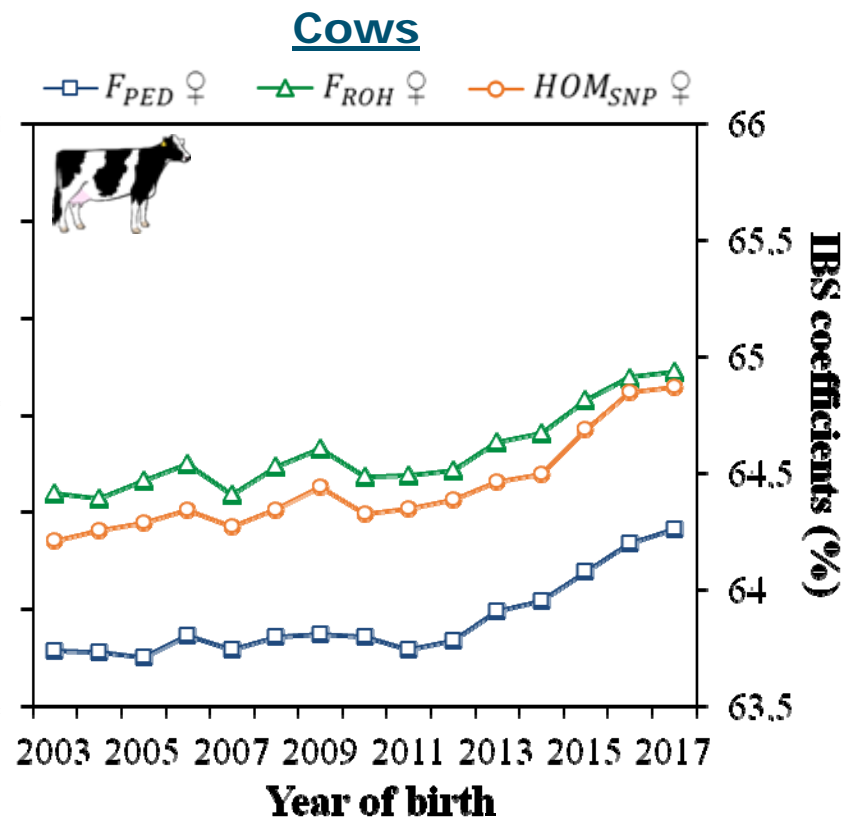

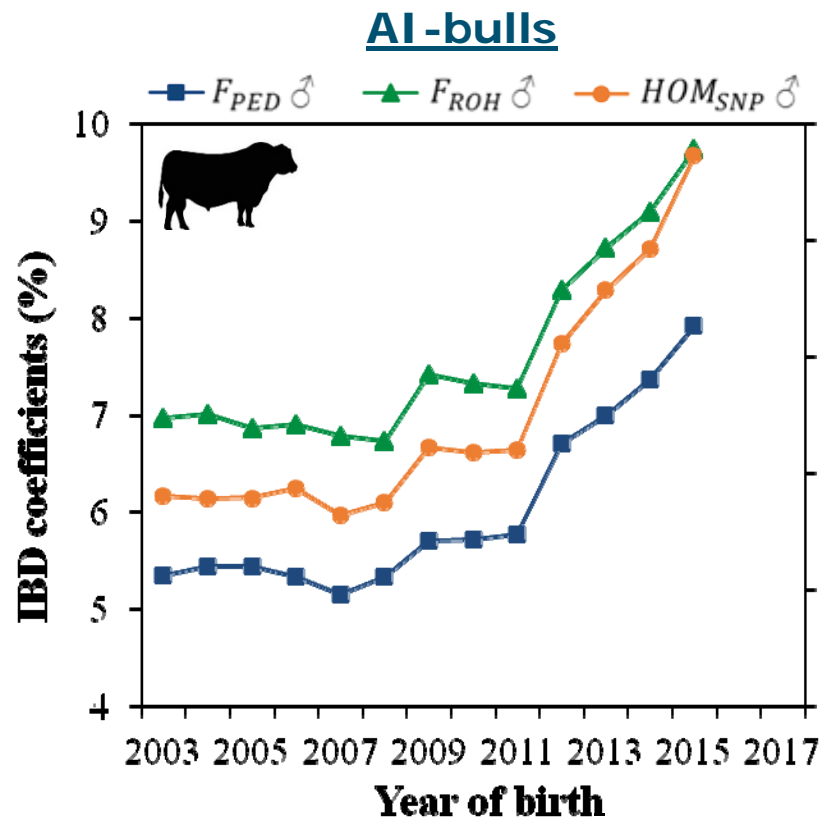

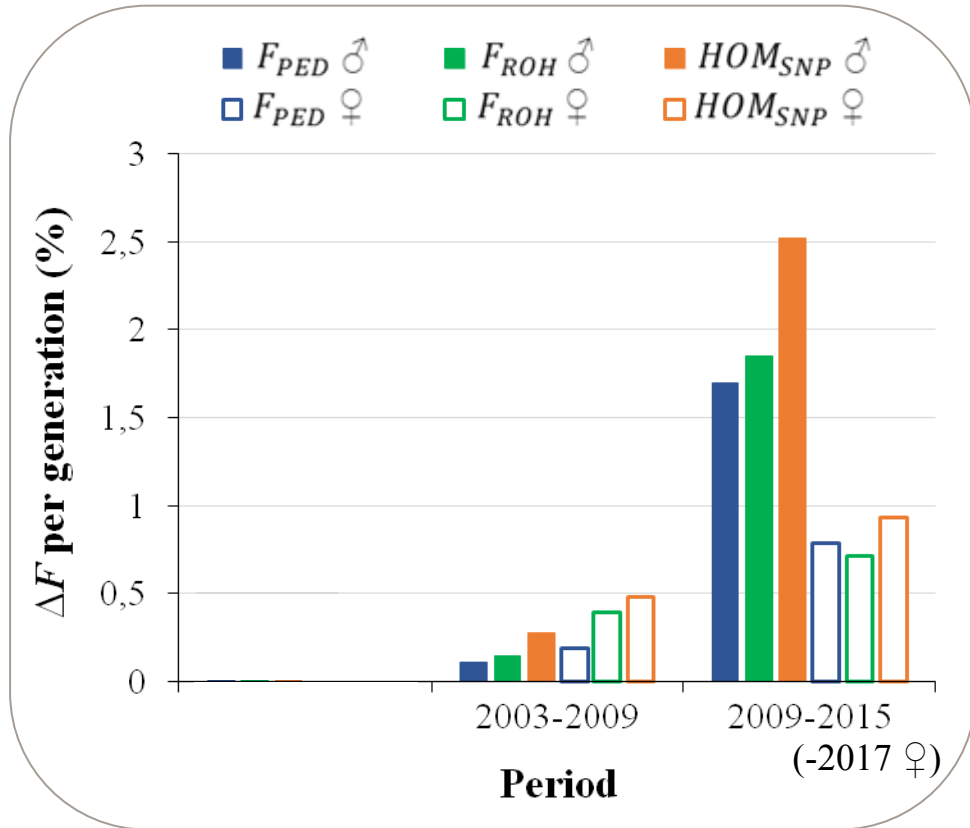

# Results: genome-wide trends

# Results: genome-wide trends

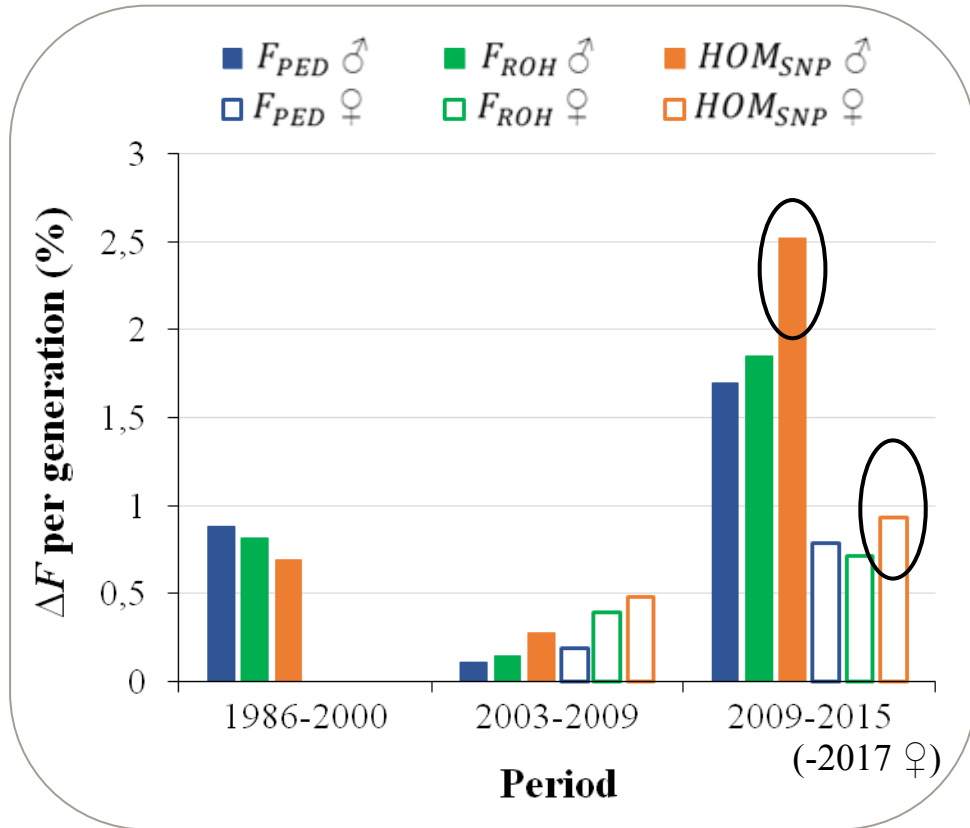

# Results: rate of inbreeding ( $\Delta F$ )

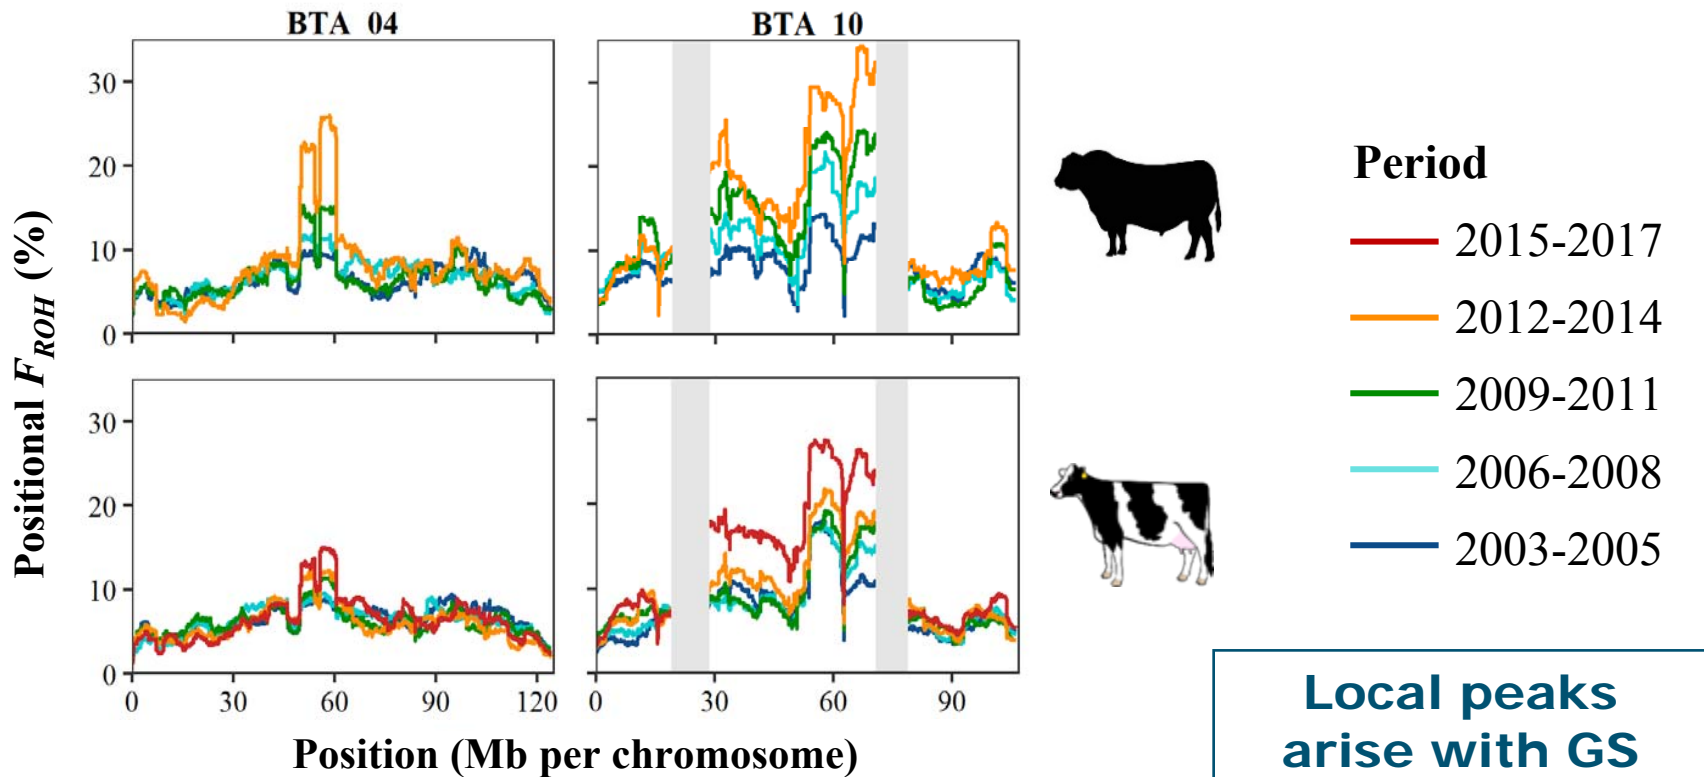

- Since 2009:
  - $N_e = 20-30$  for AI-bulls
  - $N_e = 54-70$  for cows

# Results: rate of inbreeding ( $\Delta F$ )

- Since 2009:
  - $N_e = 20-30$  for AI-bulls
  - $N_e = 54-70$  for cows
  - $\Delta IBS > \Delta IBD$

# Results: region-specific $F_{ROH}$

# Conclusions

---

- Genome-wide: GS accompanied by high  $\Delta F$ 
  - Per year & generation
  - Especially in AI-bulls
  - $\Delta IBS > \Delta IBD$
  
- Region-specific: heterogeneity in  $F$  and  $\Delta F$ 
  - Local peaks with GS

Thank you for your attention
