The Transition Period

Energy Deficit

Hyperketonemia (HYK)

Result of elevated ketone bodies in blood

Associated with negative health events

Decreased milk production

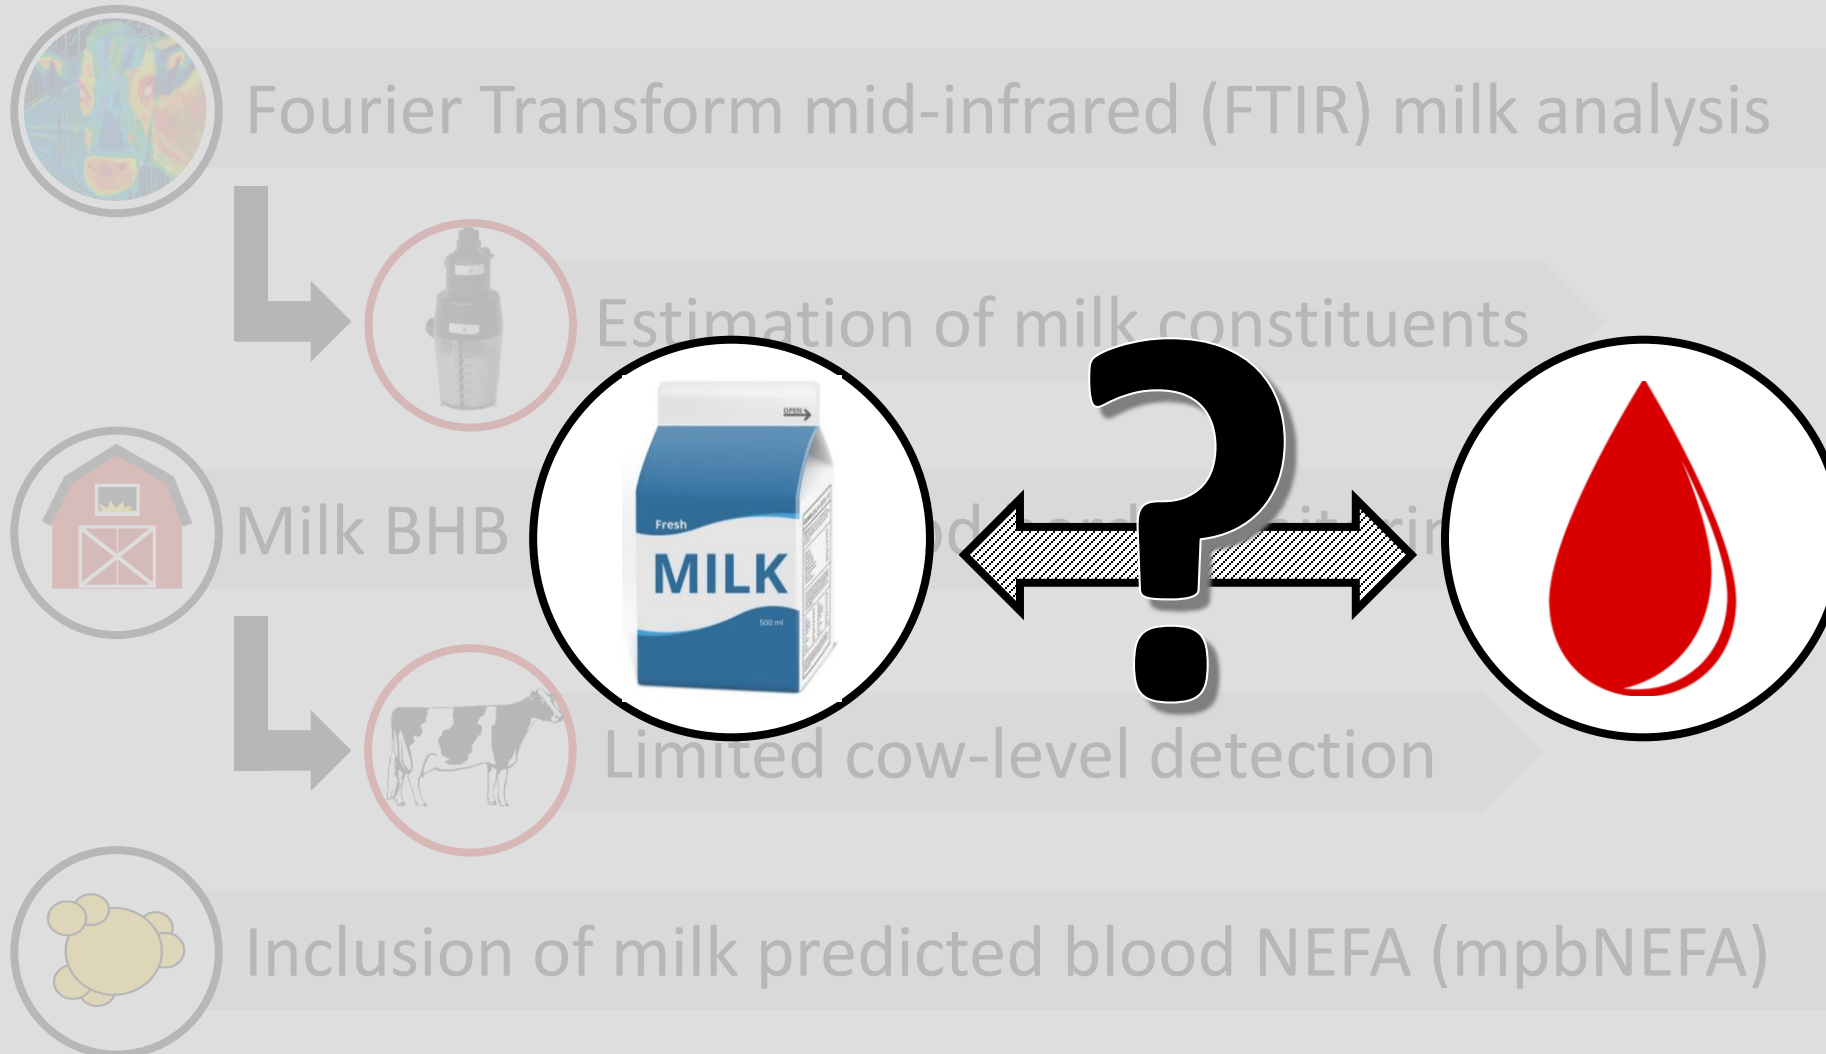

Can quantify BHB in blood

Costly and labor intensive

Monitoring HYK Through Milk

Objectives

- 1) Determine the diurnal variation in plasma BHB and NEFA, mBHB and mpbNEFA, and milk fatty acids
- 2) Explore the effects of HYK on diurnal patterns of blood and milk constituents

Materials & Methods: Study Timeline

- 28 multiparous Holstein cows
- Between 3 - 9 DIM
- Housed in tie-stalls at Cornell University Ruminant Center
- June & July 2019

Materials & Methods: Sample Collection

Materials & Methods: Sample Analysis

- Plasma samples analyzed for BHB and NEFA at NY State Animal Health and Diagnostic Center (Ithaca, NY)
- Milk samples (3X per day) analyzed for mBHB and mpbNEFA by FTIR at Barbano Lab (Cornell University)

Materials & Methods: Statistical Analysis

Results: Plasma BHB, all cows

Results: Plasma BHB, by HYK group

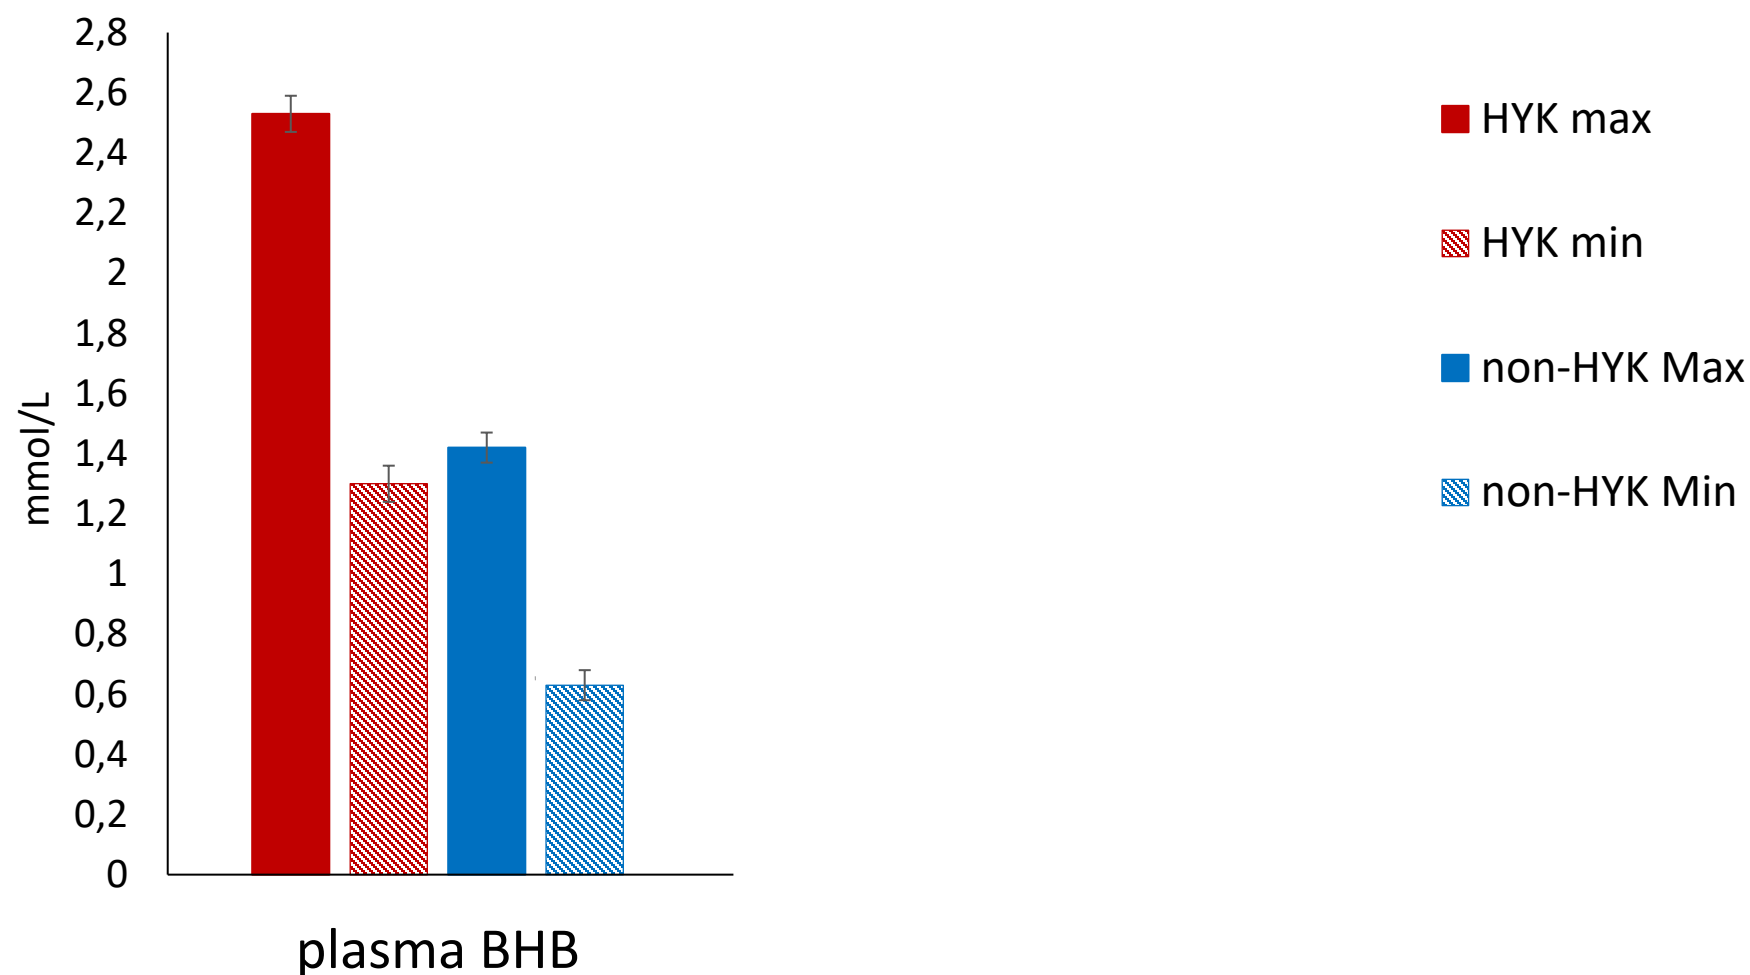

Results: Plasma NEFA, all cows

Results: Plasma NEFA, by HYK group

Results: Magnitude of Daily Change in Blood

Conclusions - Blood

- Diurnal patterns of plasma metabolites
- HYK status affected daily amplitude of change for plasma metabolites
- What happened in milk?

Results: Milk and Blood Metrics

Blood samples were collected every 2 hours within each day, while milk samples were collected at 8 hour intervals within each day.

We hypothesize that the milk on an every 8 hour 3X milking system would reflect the characteristics of the blood for the 8 hour period prior to milking.

Thus, every two hour blood data was averaged to reflect the mean blood NEFA and BHB for the 8 hour period prior to each milking.

Results: Milk Predicted Blood NEFA and Blood NEFA

Results: Milk De novo, mixed origin, and preformed FA

Results: Milk De novo, mixed origin, and preformed FA

Conclusions - Milk

- Diurnal patterns of milk estimated blood NEFA and milk fatty acids were consistent with patterns in the blood.
- HYK status affected daily amplitude and overall relative percentage of milk fatty acid groups.

Implications & Future Directions

- FTIR estimates of mBHB and mpbNEFA as a tool to diagnose HYK
- Milk constituents provide more stable estimate during a 24 h period of energy status than a single blood sample.
